

Demo Meeting: AI Meeting Chrome Extension

Participants: Yashraj, Balaji

Topic: Chrome Extension for Meeting Recording, Transcription, AI Summaries, and Follow-up Questions

Yashraj:

Hey Balaji, so the main idea I wanted to discuss today is the Chrome extension we've been working on. The goal is to make it similar to tools like Scribble and other meeting-recording extensions, but with a stronger focus on interacting with the meeting after it's over.

Balaji:

Right. So basically, it should record the meeting and then give us the transcript and summary?

Yashraj:

Exactly. The extension would work with platforms like Google Meet. Once the user joins a meeting, the extension detects the meeting and starts capturing the audio and generating a real-time transcript.

Balaji:

Would the user have to manually start the recording?

Yashraj:

We can give them both options. By default, when they enter a supported meeting, the extension can show a small floating widget saying something like "Start Recording." The user can start or stop recording from there.

Balaji:

Okay. And after the meeting?

Yashraj:

Once the meeting ends, the transcript gets processed. We can generate an AI summary with different sections — meeting overview, key discussion points, decisions, action items, and follow-ups.

Balaji:

That's pretty standard for meeting assistants. What's the main differentiator?

Yashraj:

The follow-up question functionality. That's the interesting part.

Balaji:

So the user can ask questions about the meeting?

Yashraj:

Yes. For example, imagine we had a one-hour meeting about a product launch. After the meeting, I could ask, "What did Balaji say about the launch timeline?"

Balaji:

And it searches the transcript and gives me the relevant answer?

Yashraj:

Exactly. The system can retrieve the relevant transcript sections and use the AI model to answer the question with context. Ideally, it should also show the timestamp where that discussion happened.

Balaji:

That would be useful. So I could click the timestamp and jump directly to that part of the recording?

Yashraj:

Yes. That's one of the features I think would make the extension much more useful than just having a static transcript.

Balaji:

What other features are we planning?

Yashraj:

We can have automatic action-item detection. For example, if someone says, "Yashraj will finish the API integration by Friday," the system should identify that as an action item and associate it with Yashraj and the deadline.

Balaji:

Can we also identify who said what?

Yashraj:

Yes. Speaker identification would be important. The transcript should ideally show different participants, and the AI should understand the conversation in terms of who made each statement.

Balaji:

What about meeting titles and organizing all these recordings?

Yashraj:

We can have a dashboard where users see all their meetings. Each meeting can have the title, date, duration, participants, summary, transcript, recording, and AI-generated insights.

Balaji:

And the Chrome extension itself should stay lightweight, right?

Yashraj:

Exactly. The extension should mainly handle meeting detection, recording controls, and quick access. The heavier processing can happen on the backend.

Balaji:

What happens if the user wants to ask another question a week later?

Yashraj:

The meeting data remains stored. So they can open an old meeting and continue asking questions. The AI can use that meeting's transcript as its knowledge base.

Balaji:

Could we ask questions across multiple meetings too?

Yashraj:

Yes, that's another feature we can add later. For example, "What did we decide about the authentication system across our last three meetings?" The system could search multiple meeting transcripts and provide a consolidated answer.

Balaji:

That sounds more like an AI knowledge base for meetings.

Yashraj:

Exactly. That's where I think we can differentiate the product. Recording is the basic layer. Transcription and summarization are the next layer. The conversational AI layer is what makes the meeting data actually useful.

Balaji:

Makes sense. What should we build for the first version?

Yashraj:

For the MVP, I'd keep it focused: Google Meet support, recording, transcription, speaker identification, meeting summary, action items, searchable transcript, and the ability to ask follow-up questions about a meeting.

Balaji:

And then we can add Slack, Zoom, Microsoft Teams, calendar integrations, and cross-meeting search later?

Yashraj:

Exactly. We should first make the core experience reliable before expanding to more platforms.

Balaji:

Okay. I think the follow-up question feature should be the main thing we showcase in the demo.

Yashraj:

Agreed. The demo should show a meeting being recorded, the transcript being generated, the meeting ending, the AI summary appearing, and then the user asking something like, "What were the three main decisions we made?" Then we show the answer with references to the transcript and timestamps.

Balaji:

Perfect. That gives us a clear end-to-end flow.

Yashraj:

Yep. That's the experience we're aiming for — not just recording meetings, but making every meeting searchable, understandable, and conversational after it ends.
